1. Background

The burn wound provides suitable conditions for bacterial growth. Bacterial infection is a serious factor of mortality in burn patients. Incidentally, approximately 75% of the mortality due to burn wounds is associated with infections (1). An opportunistic, nosocomial pathogen of immunocompromised patients, *Pseudomonas aeruginosa*, typically infects the burns wounds. A study revealed that *P. aeruginosa* was isolated from 73.9% of the burn patients in Iran (2, 3). In addition, many studies showed that colonization of these bacteria in burn wounds is a main cause of mortality in burn patients in burn treatment centers in Iran (2).

To treat such infections, carbapenems such as imipenem are identified as the most effective agent against *P. aeruginosa* (4). Although imipenem is known as a potential last treatment option for patients with burn lesions, it was revealed that one of the most concerning characteristics of *P. aeruginosa* species is their high resistance to imipenem in hospitalized burn patients in recent years. Were reported 16% - 100% in Tehran hospitals in various studies (5).

Although metallo-β-lactamases (MBLs) are one of the most important mechanisms resulting in treatment failure in carbapenem therapy of *P. aeruginosa* infections, these isolates also produce β-lactamases of class A and D. Class A extended-spectrum β-lactamases (ESBLs) including TEM, SHV, GES, PER, VEB, CTX-M and IBC families are also found in *P. aeruginosa* strains. extended-spectrum β-lactamases from the class D, OXA-type enzymes are also detected in *P. aeruginosa* (6). Also recently, the number of *P. aeruginosa* isolates producing KPC-type carbapenemases raised significantly (7). Plasmid acquired Ambler class A ESBLs such as GES, PER, SHV and TEM types were normally found in *Enterobacteriaceae*. Class A ESBLs are recently identified in *P. aeruginosa* but they are reported in a limited areas (8). Compared with the enterobacterial species, in which TEM and SHV ESBLs are found most frequently, OXA and PSE types are the most common β-lactamases in *P. aeruginosa* (9).

2. Objectives

To the best of the authors’ knowledge, there is not enough information regarding the prevalence of class A and D ESBLs and the type of involved genes in imipenem

---

Background: *Pseudomonas aeruginosa* remains a leading cause of severe wound infection and mortality in burn patients.

Objectives: The current study aimed to determine the prevalence of Ambler class A and D β-lactamases among *P. aeruginosa* isolated from infected burn injuries in Tehran, Iran.

Patients and Methods: Bacteriological samples were taken from burn patients with clinical symptoms of burn infection. Fifty Gram-negative, oxidase-positive, catalase-positive bacilli, grown at 42°C and production of pigment on Mueller-Hinton agar were identified as *P. aeruginosa*. All of the 50 isolates were examined for antibiotic susceptibility via disk diffusion method, and production of Ambler class A and D β-lactamases by phenotypic screening test. The presence of Ambler class A and D β-lactamases was confirmed by polymerase chain reaction technique.

Results: The results showed that the majority of isolates (88%) were multi-drug resistant. Out of these 50 imipenem resistant isolates, 7 (14%), 18 (36%), 18 (36%) and 18 (36%) strains were positive for *bla*<sub>PER</sub>, *bla*<sub>OXA-10</sub>, *bla*<sub>TEM</sub> and *bla*<sub>SHV</sub> genes alone or in combination, respectively. None of the isolates possessed *bla*KPC- or *bla*GES genes.

Conclusions: The current study highlights that the high level of resistance to many antibacterial agents and a gradual increase in the degree of PER, OXA-10, SHV and TEM ESBLs among the majority of imipenem resistant *P. aeruginosa* isolated from patients with burn infection is an enormous threat in burn centers in Iran.

Keywords: Imipenem; *bla*<sub>PER</sub>, *bla*<sub>OXA-10</sub>, *bla*<sub>TEM</sub>, *bla*<sub>SHV</sub>; *Pseudomonas aeruginosa*
resistant *P. aeruginosa* in burn patients in Iran. The current study aimed to investigate the prevalence of GES, PER, SHV, TEM and OXA-10 ESBLs as well as KPC carbapenemases among imipenem resistant *P. aeruginosa* strains isolated from the burn patients hospitalized in several burn treatment centers in Tehran, Iran (2).

3. Patients and Methods

3.1. Bacterial Isolates
Fifty imipenem resistant *P. aeruginosa* species were isolated from hospitalized burn patients from 2009 to 2010 in Tehran, Iran. The isolates were identified as *P. aeruginosa* by conventional biochemical tests such as oxidase and catalase production, growth at 42°C, and production of pigment on Mueller-Hinton agar (Merck, Germany). The isolates were stored at -20°C in brain-heart infusion broth (Merck, Germany) with 15% glycerol for future investigations.

3.2. Susceptibility Tests and Confirmation of ESBLs Production
Antimicrobial susceptibility to various antibiotics was carried out using the disc-diffusion method recommended by the clinical and laboratory standards institute (CLSI) guidelines (10). Eleven antibacterial discs including cefotaxime (CTX; 30 µg), ceftazidime (CAZ; 30 µg), aztreonam (ATM; 30 µg), gentamicin (GM; 10 µg), ciprofloxacin (CIP; 5 µg), amikacin (AN; 30 µg), tobramycin (TOB; 10 µg), cefepime (CPM; 30 µg), pipracillin (PIP; 100 µg), cefixime (CFM; 5 µg), and ticarcillin (TIC; 75 µg) (MAST, UK) were used. ESBLs phenotypic confirmatory tests were performed by combined disc tests, using CTX and CTX/clavulanic acid (30/10 µg) and CAZ and CAZ/clavulanic acid (30/10 µg) (11). The inhibitory zone diameter ≥ 5 mm was considered positive for ESBLs production.

3.3. Detection of blaGES, blaPER, blaSHV, blaTEM, blaOXA-10 and blaKPC Genes by Polymerase Chain Reaction
DNA was extracted by the boiling method (12) and PCR analysis was carried out on all 50 isolates to evaluate the prevalence of the blaGES, blaPER, blaSHV, blaTEM, blaOXA-10 ESBLs and blaKPC carbapenemases genes. The DNA amplification program and the specific primers (TAKAPOUZIST, IRAN) used for standard PCR amplification procedures are shown in Table 1 (11, 13-17). To detect DNA fragments PCR products were detected by gel electrophoresis in 1.5% agarose.

4. Results
The results of antibiogram testing showed that all isolates (100%) were resistant to CTX, CPM, PIP, CFM and TIC. Meanwhile, the findings revealed that 49 (98%) isolates were resistant to CAZ, CIP and 48 (96%) isolates were resistant to ATM, AN, GM and TOB. Most of the isolates were resistant to various classes of antibacterial agents (Table 2). Among the 50 isolates, 44 (88%) were multi-drug resistant and phenotypic tests indicated that 27 (54%) strains were presumed ESBLs producers. Among the 27 strains, 23 (85.18%) were determined with zone diameters of 5 - 14 mm in combination with CAZ/clavulanic acid and 17 (62.96%) were determined with zone diameters of 5 - 12 mm in combination with CTX/clavulanic acid.

PCR analysis was carried out for all 50 isolates using primers specific to \( \text{bla}_{\text{PER}} \), \( \text{bla}_{\text{GES}} \), \( \text{bla}_{\text{OXA-10}} \), \( \text{bla}_{\text{TEM}} \), \( \text{bla}_{\text{SHV}} \) and \( \text{bla}_{\text{KPC}} \). Four of six genes were detected alone or in various combinations; 7 (14%), 18 (36%), 18 (36%), 18 (36%) strains of a total of 50 isolates were amplified as \( \text{bla}_{\text{PER}} \), \( \text{bla}_{\text{OXA-10}} \), \( \text{bla}_{\text{TEM}} \) and \( \text{bla}_{\text{SHV}} \), respectively (Figure 1). Whilst among the 27 isolates indicated as presumed ESBLs producers phenotypically, 3 (11.11%), 12 (42.85%), 14 (50%) and 14 (50%) strains were detected as \( \text{bla}_{\text{PER}} \), \( \text{bla}_{\text{OXA-10}} \), \( \text{bla}_{\text{TEM}} \) and \( \text{bla}_{\text{SHV}} \) genes, respectively. In addition, among isolates, 10 (20%) carried \( \text{bla}_{\text{TEM}} \) and \( \text{bla}_{\text{OXA-10}} \) genes, simultaneously. Also 98% of SHV, TEM and OXA-10 producing strains were resistant to all of the antibiotics used in this research. No \( \text{bla}_{\text{KPC}} \) and \( \text{bla}_{\text{GES}} \) genes were detected in the study. Table 3 shows that approximately all of the isolates harboring multiple antimicrobial resistance genes were 100% resistant to different classes of antibiotics except CIP.

5. Discussion

The application of antibiotics is one of the most important scientific attainments of the 20th century. However, prevalent antibiotic use increases antibiotic-resistant pathogens, including multidrug resistant isolates (18). Antibiotic resistance of pathogenic bacteria is a major global danger and Realization of the resistance mechanisms is critical to development of novel therapeutic options (18). Pseudomonas aeruginosa is the predominant bacterial pathogen in patients with burn injuries. The resistance of this microorganism to antibiotics is a worrisome problem in hospitalized patients with burn injuries. Extended spectrum β-lactamases, carbapenemases, metallo β-lactamases and AmpC β-lactamases producing organisms are the main problems to treat the infected burn patients in burn centers (1). One of the most important ways to select an effective method to reduce such infections is specifying the relationship between genotype and drug susceptibility (1). Multidrug-resistant P. aeruginosa isolates re a worrying matter from burn patients in Iran (19). Several classes of ESBLs such as OXA, PER, TEM, SHV and GES are newly detected in P. aeruginosa. Also recently, the number of P. aeruginosa isolates producing KPC-type carbapenemases has significantly raised (7).

The findings of the present study explained that high levels of resistance to many antimicrobial antibiotics existed among P. aeruginosa isolated from the infected wounds of burn patients and the majority of isolates (88%) were multi-drug resistant. All isolates were totally resistant to CTX, CPM, PIP, CFM and TIC; whereas the minimum resistance rate (96%) was demonstrated for ATM, GM, TOB and AN. Results of the previous studies approved resistance to a large number of antibiotics usually used to treat burn injuries caused by P. aeruginosa in the Iranian hospitals (19). For instance, Shahcheraghi et al. reported that nosocomial P. aeruginosa isolates were resistant to cefotaxime (56%) and cefazidime (25%) (20). In another study, the rates of resistance were as follows: cefazidime (74.8%) and cefotaxime (50.4%) (19). Moreover, among 27 isolates, phenotypically positive for ESBLs production, 0 (0%), 12 (42.85%), 14 (50%) and 14 (50%) strains were detected as blaPER, blaOXA-10, blaTEM and blaSHV genes, respectively. Shahcheraghi et al. reported that the frequency of blaPER, blaTEM, blaSHV and blaGES were 17%, 9%, 22% and 0%, respectively (20).

To find more information about the prevalence and type of the relevant genes involved in the multi-drug resistance of nosocomial P. aeruginosa isolates, the PCR experiments were performed for all 50 isolates. Of the 50 isolates, 7 (14%), 18 (36%), 18 (36%) and 18 (36%) strains were positive for blaPER, blaOXA-10, blaTEM and blaSHV alone or in various combinations, respectively. In addition, earlier reports from Iran also showed that the prevalence of blaPER-1 and blaOXA-10 were 49.25% and 74.62%, respectively (2). The observations suggest that the prevalence of blaOXA-10, blaTEM and blaSHV among all of the 50 isolates were relatively high in the present work. Except in Turkey, in which PER (86%) and OXA-10 (55%) as well as Saudi Arabia in which OXA-10 (56%) and GES (20%) producing P. aeruginosa strains were reported (21, 22), no current data existed on the real prevalence of these genes in the countries neighboring Iran. It is possible that the distribution of PER and OXA-10 probably associated with the immigration and traveling between Iran and Turkey.

A study conducted in Taiwan showed that TEM, SHV-18 and OXA-10 genes exist in 100%, 91.3% and 21.7% of the total P. aeruginosa strains, respectively (23). Based on the results of PCR assay, there were no blaGES and blaKPC genes in the 50 tested isolates of P. aeruginosa in the current study. There are several case reports on the isolation of KPC-producing P. aeruginosa and Klebsiella species in burned patients in Iran (24, 25). There seems to be a gradual increase in KPC-producing P. aeruginosa in the burn centers of Iran. From the clinical point of view, occurrence of KPC-producer Gram-negative bacteria among the burned patients causes a much higher degree of resistance to many antibacterial agents including β-lactams, quinolones and aminoglycosides (26). These findings increase the concern about the future of antibiotic therapy for KPC-producing P. aeruginosa strains.

In conclusion, the current study described that the high rates of resistance to different antibacterial agents and a gradual increase in the degree of PER, OXA-10, SHV and TEM ESBLs among the majority of imipenem resistant P. aeruginosa isolated from the burned patients causes an enormous threat in burn centers of Iran. Therefore, molecular epidemiologic studies play a significant role in the evaluation of transmission ways of the pathogen for infection control.

Acknowledgements

The authors are very grateful to Professor Nordmann for providing the control strain harboring blaGES and Dr. Shahcheraghi for providing the control strain harboring blaKPC genes.

Authors’ Contributions

All the experimental works and data analysis are done by Sanaz Pakbaten Toukanlou and Rahim Pirhajati Mahabadi; Dr. Shahin Najar Peerayeh supervised the research.

Funding/Support

This work was financially supported by grants from faculty of medical sciences, Tarbiat Modares university, Tehran, Iran.
